

Does 9% tool-norm shrinkage explain the $\sim +1.7$ uniform shift? ($\sim 76\%$ explained; mean $|\text{resid}|=0.51$)

Predicted vs observed metric shift

9% norm-shrinkage magnitude check

Formula: $(\Delta_{abs} - \Delta_{rel}) \approx (1 - N_{tool}/N_{prose}) \cdot \varepsilon_{prose}^*$ with $N_t/N_p \approx 0.911$. Random residual opposite sign vs safety/learned.
